Argentina

Capital City : "Buenos Aires"
Official Language: "Spanish"
Monetary Unit: "peso (ARS)"

General information

The information on these pages should be used to research health risks and to inform the pre-travel consultation. For advice regarding safety and security please check the UK Foreign and Commonwealth Office (FCO) website.

Travellers should ideally arrange an appointment with their health professional at least four to six weeks before travel. However, even if time is short, an appointment is still worthwhile. This appointment provides an opportunity to assess health risks taking into account a number of factors including destination, medical history, and planned activities. For those with pre-existing health problems, an earlier appointment is recommended.

All travellers should ensure they have adequate travel health insurance.

A list of useful resources including advice on how to reduce the risk of certain health problems is available below.

Resources

- Food and water hygiene
- Insect and tick bite avoidance
- Personal safety
- Sexually transmitted infections
Vaccine recommendations

Details of vaccination recommendations and requirements are provided below.

All Travellers

Travellers should be up to date with routine vaccination courses and boosters as recommended in the UK. These vaccinations include for example measles-mumps-rubella (MMR) vaccine and diphtheria-tetanus-polio vaccine.

Country specific diphtheria recommendations are not provided here. Diphtheria tetanus and polio are combined in a single vaccine in the UK. Therefore, when a tetanus booster is recommended for travellers, diphtheria vaccine is also given. Should there be an outbreak of diphtheria in a country, diphtheria vaccination guidance will be provided.

Those who may be at increased risk of an infectious disease due to their work, lifestyle choice, or certain underlying health problems should be up to date with additional recommended vaccines. See the individual chapters of the ‘Green Book’ Immunisation against infectious disease for further details.

Certificate Requirements

- There are no certificate requirements under International Health Regulations.
- There is a risk of yellow fever transmission in parts of Argentina (see ‘Some Travellers’ section below).

Most Travellers

The vaccines in this section are recommended for most travellers visiting this country. Information on these vaccines can be found by clicking on the blue arrow. Vaccines are listed alphabetically.

Tetanus

Tetanus is caused by a toxin released from Clostridium tetani and occurs worldwide. Tetanus bacteria are present in soil and manure and may be introduced through open wounds such as a puncture wound, burn or scratch.

Prevention

Travellers should thoroughly clean all wounds and seek appropriate medical attention.

Tetanus vaccination

- Travellers should have completed a primary vaccination course according to the UK schedule.
- If travelling to a country where medical facilities may be limited, a booster dose of a tetanus-
containing vaccine is recommended if the last dose was more than ten years ago even if five doses of vaccine have been given previously.

Country specific information on medical facilities may be found in the ‘health’ section of the FCO foreign travel advice website.

Some Travellers

The vaccines in this section are recommended for some travellers visiting this country. Information on when these vaccines should be considered can be found by clicking on the arrow. Vaccines are listed alphabetically.

**Hepatitis A**

Hepatitis A is a viral infection transmitted through contaminated food and water or by direct contact with an infectious person. Symptoms are often mild or absent in young children, but the disease becomes more serious with advancing age. Recovery can vary from weeks to months. Following hepatitis A illness immunity is lifelong.

Those at increased risk include travellers visiting friends and relatives, long-stay travellers, and those visiting areas of poor sanitation.

**Prevention**

All travellers should take care with personal, food and water hygiene.

**Hepatitis A vaccination**

Vaccination is recommended for those whose activities put them at increased risk. This includes:

- those who are staying with or visiting the local population.
- frequent and/or long-stay travellers to areas where sanitation and food hygiene are likely to be poor.
- adventure travellers visiting rural areas and staying in basic accommodation such as backpackers.
- those with existing medical conditions such as liver disease or haemophilia.
- men who have sex with men.
- injecting drug users.
- those who may be exposed to the virus through their work.
- those going to areas of hepatitis A outbreaks who have limited access to safe water and medical care.
Hepatitis B

Hepatitis B is a viral infection; it is transmitted by exposure to infected blood or body fluids. This mostly occurs during sexual contact or as a result of blood-to-blood contact (for example from contaminated equipment during medical and dental procedures, tattooing or body piercing procedures, and sharing of intravenous needles). Mothers with the virus can also transmit the infection to their baby during childbirth.

Hepatitis B in Argentina

2% or more of the population are known or thought to be persistently infected with the hepatitis B virus (intermediate/high prevalence).

Prevention

Travellers should avoid contact with blood or body fluids. This includes:

- avoiding unprotected sexual intercourse.
- avoiding tattooing, piercing, public shaving, and acupuncture (unless sterile equipment is used).
- not sharing needles or other injection equipment.
- following universal precautions if working in a medical/dental/high risk setting.

A sterile medical equipment kit may be helpful when travelling to resource poor areas.

Hepatitis B vaccination

Vaccination could be considered for all travellers, and is recommended for those whose activities or medical history put them at increased risk including:

- those who may have unprotected sex.
- those who may be exposed to contaminated needles through injecting drug use.
- those who may be exposed to blood or body fluids through their work (e.g. health workers).
- those who may be exposed to contaminated needles as a result of having medical or dental care e.g. those with pre-existing medical conditions and those travelling for medical care abroad including those intending to receive renal dialysis overseas.
- long-stay travellers.
- those who are participating in contact sports.
- families adopting children from this country.

Hepatitis B in brief
Rabies

Rabies is a viral infection which is usually transmitted following contact with the saliva of an infected animal most often via a bite, scratch or lick to an open wound or mucous membrane (such as on the eye, nose or mouth). Although many different animals can transmit the virus, most cases follow a bite or scratch from an infected dog. In some parts of the world, bats are an important source of infection.

Rabies symptoms can take some time to develop, but when they do, the condition is almost always fatal.

The risk of exposure is increased by certain activities and length of stay (see below). Children are at increased risk as they are less likely to avoid contact with animals and to report a bite, scratch or lick.

Rabies in Argentina

Rabies has been reported in domestic and wild animals in this country. Bats may also carry rabies-like viruses.

Prevention

- Travellers should avoid contact with all animals. Rabies is preventable with prompt post-exposure treatment.
- Following a possible exposure, wounds should be thoroughly cleansed and an urgent local medical assessment sought, even if the wound appears trivial.
- Post-exposure treatment and advice should be in accordance with national guidelines.

Rabies vaccination

Pre-exposure vaccinations are recommended for travellers whose activities put them at increased risk including:

- those at risk due to their work (e.g. laboratory staff working with the virus, those working with animals or health workers who may be caring for infected patients).
- those travelling to areas where access to post-exposure treatment and medical care is limited.
- those planning higher risk activities such as running or cycling.
- long-stay travellers (more than one month).

A full course of pre-exposure vaccines simplifies and shortens the course of post-exposure treatment and removes the need for rabies immunoglobulin which is in short supply world-wide.

Rabies in brief
**Typhoid**

Typhoid is a bacterial infection transmitted through contaminated food and water. Previous typhoid illness may only partially protect against re-infection.

Travellers who will have access to safe food and water are likely to be at low risk. Those at increased risk include travellers visiting friends and relatives, frequent or long-stay travellers to areas where sanitation and food hygiene are likely to be poor.

**Typhoid in Argentina**

Typhoid fever is known or presumed to occur in this country.

**Prevention**

All travellers should take care with personal, food and water hygiene.

**Typhoid vaccination**

- Both oral and injectable typhoid vaccinations are available, and vaccination is recommended for laboratory personnel who may handle the bacteria for their work.
- Vaccination could be considered for those whose activities put them at increased risk (see above).

**Yellow Fever**

Yellow fever is a viral infection transmitted by mosquitoes which predominantly feed between dawn and dusk, but may also bite at night, especially in the jungle environment. Symptoms may be absent or mild, but in severe cases it can cause internal bleeding, organ failure and death.

**Yellow fever in Argentina**

There is a risk of yellow fever transmission in parts of this country, see below.

**Prevention**

Travellers should avoid mosquito bites at all times.

**Yellow fever vaccination**
• Vaccination is recommended for those aged 9 months and older travelling to Corrientes and Misiones Provinces including the Iguacu Falls.
• Vaccination is generally not recommended for travel to areas with low potential for exposure to yellow fever: Formosa Province and designated areas of Chaco, Jujuy and Salta Provinces (see map) but could be considered for a small subset of travellers who are at increased risk because of:
  - Prolonged travel.
  - Heavy exposure to mosquitoes.
  - Inability to avoid mosquito bites.
• Vaccination is not recommended for travellers whose itineraries are limited to areas and provinces not listed above.
• See vaccine recommendation map below.

The yellow fever vaccine is not suitable for all travellers, there are specific undesirable effects associated with it. This vaccine is only available at registered yellow fever vaccination centres. Health professionals should carefully assess the risks and benefits of the vaccine, and seek specialist advice if necessary.

Yellow fever in brief

Yellow fever vaccine recommendations in Argentina

Map provided by the Travelers' Health Branch, Centers for Disease Control and Prevention
Current as of July 2017. This map, which aligns with recommendations also published by the World Health Organization (WHO), is an updated version of the 2010 map created by the Informal WHO Working Group on the Geographic Risk of Yellow Fever.

1. Yellow fever (YF) vaccination is generally not recommended in areas where there is low potential for YF virus exposure. However, vaccination might be considered for a small subset of travelers to these areas who are at increased risk for exposure to YF virus because of prolonged travel, heavy exposure to mosquitoes, or inability to avoid mosquito bites. Consideration for vaccination of any traveler must take into account the traveler’s risk of being infected with YF virus, country entry requirements, and individual risk factors for serious vaccine-associated adverse events (e.g. age, immune status).

**Malaria**

Malaria is a serious illness caused by infection of red blood cells with a parasite called Plasmodium. The disease is transmitted by mosquitoes which predominantly feed between dusk and dawn.

Symptoms usually begin with a fever (high temperature) of 38°C (100°F) or more. Other symptoms may include feeling cold and shivery, headache, nausea, vomiting and aching muscles. Symptoms may appear between eight days and one year after the infected mosquito bite.

Prompt diagnosis and treatment is required as people with malaria can deteriorate quickly. Those at higher risk of malaria, or of severe complications from malaria, include pregnant women, infants and young children, the elderly, travellers who do not have a functioning spleen and those visiting friends and relatives.

**Prevention**

Travellers should follow an ABCD guide to preventing malaria:

- **Awareness of the risk** – Risk depends on the specific location, season of travel, length of stay, activities and type of accommodation.

- **Bite prevention** – Travellers should take mosquito bite avoidance measures.

- **Chemoprophylaxis** – Travellers should take antimalarials (malaria prevention tablets) if appropriate for the area (see below). No antimalarials are 100% effective but taking them in combination with mosquito bite avoidance measures will give substantial protection against malaria.

- **Diagnosis** – Travellers who develop a fever of 38°C [100°F] or higher more than one week after being in a malaria risk area, or who develop any symptoms suggestive of malaria within a year of return should seek immediate medical care. Emergency standby treatment may be considered for those going to remote areas with limited access to medical attention.

**Risk Areas**

- There is a very low risk of malaria in low altitude areas of Salta provinces bordering Bolivia and in Chaco, Corrientes and Misiones provinces close to the border with Paraguay and Brazil: **awareness of risk** and **bite avoidance** recommended.

- There is no risk of malaria in Iguazu Falls and the rest of Argentina: **bite avoidance**
There are no antimalarial drugs recommended for Argentina.

**Antimalarial Recommendations Map**

- Open map in a new window

**Resources**

- Malaria in brief
- Malaria factsheet
- Insect and tick bite avoidance
- Children’s antimalarial dose table
- Malaria prevention guidelines for travellers from the UK

**Other risks**

There are some risks that are relevant to all travellers regardless of destination. These may for example include road traffic and other accidents, diseases transmitted by insects or ticks, diseases transmitted by contaminated food and water, sexually transmitted infections, or health issues related to the heat or cold. Some additional risks (which may be present in all or part of this country) are mentioned below and are presented alphabetically.
Altitude

There is a risk of altitude illness when travelling to destinations of 2,500 metres (8,200 feet) or higher. Important risk factors are the altitude gained, rate of ascent and sleeping altitude. Rapid ascent without a period of acclimatisation puts a traveller at higher risk.

There are three syndromes; acute mountain sickness (AMS), high-altitude cerebral oedema (HACE) and high-altitude pulmonary oedema (HAPE). HACE and HAPE require immediate descent and medical treatment.

Altitude illness in Argentina

There is a point of elevation in this country higher than 2,500 metres. An example place of interest: Aconcagua 6,960m.

Prevention

- Travellers should spend a few days at an altitude below 3,000m.
- Where possible travellers should avoid travel from altitudes less than 1,200m to altitudes greater than 3,500m in a single day.
- Ascent above 3,000m should be gradual. Travellers should avoid increasing sleeping elevation by more than 500m per day and ensure a rest day (at the same altitude) every three or four days.
- Acetazolamide can be used to assist with acclimatisation, but should not replace gradual ascent.
- Travellers who develop symptoms of AMS (headache, fatigue, loss of appetite, nausea and sleep disturbance) should avoid further ascent. In the absence of improvement or with progression of symptoms the first response should be to descend.
- Development of HACE or HAPE symptoms requires immediate descent and emergency medical treatment.

Biting insects or ticks

Insect or tick bites can cause irritation and infections of the skin at the site of a bite. They can also spread certain diseases.

Diseases in South America
There is a risk of insect or tick borne diseases in some areas of South America. This includes diseases such as American Trypanosomiasis (Chagas Disease), chikungunya, leishmaniasis and West Nile virus.

**Prevention**

All travellers should avoid insect and tick bites day and night. There are no vaccinations (or medications) to prevent these diseases.

Further information about specific insect or tick borne diseases for this country can be found, if appropriate on this page, in other sections of the country information pages and the insect and tick bite avoidance factsheet.

**Dengue**

Dengue is a viral infection transmitted by mosquitoes which predominantly feed between dawn and dusk. It causes a flu-like illness, which can occasionally develop into a more serious life-threatening form of the disease. Severe dengue is rare in travellers.

The mosquitoes that transmit dengue are most abundant in towns, cities and surrounding areas. All travellers to dengue areas are at risk.

**Dengue in Argentina**

There is a risk of dengue in the provinces north of and including the province of Buenos Aires. Affected provinces include: Buenos Aires, Buenos Aires D.F., Catamarca, Chaco, Cordoba, Corrientes, Entre Rios, Formosa, Jujuy, Misiones, Salta, Santa Fe, Santiago Del Estero, and Tucuman.

**Prevention**

- All travellers should avoid mosquito bites particularly between dawn and dusk.
- There is no vaccination or medication to prevent dengue.

**Zika Virus**

Zika virus (ZIKV) is a viral infection transmitted by mosquitoes which predominantly feed between dawn and dusk. A small number of cases of sexual transmission of ZIKV have also been reported. Most people infected with ZIKV have no symptoms. When symptoms do occur they are usually mild and short-lived. Serious complications and deaths are not common. However, there is now scientific consensus that Zika virus is a cause of congenital Zika syndrome (microcephaly and other congenital anomalies) and Guillain-Barré syndrome.

**Zika virus in Argentina**

This country is considered to have a moderate risk of Zika virus transmission. Pregnant women should consider postponing non-essential travel until after the pregnancy. Details of specific affected areas within this country are limited; confirmed cases are reported from the provinces of Chaco, Formosa, Salta, and Tucumán. The mosquitoes that transmit ZIKV are unlikely
to be found above 2,000m altitude. There are a number of areas above 2,000m in the Andes mountains.

The map below shows areas which are above 2,000m and can be used by travellers and health professionals as a general guide to indicate potentially lower risk areas for mosquito-acquired ZIKV infection. Travellers whose itineraries are limited to areas above 2,000m are at a lower risk of acquiring ZIKV from a mosquito; however there may still be a risk of sexual transmission.

Map provided by the Travelers’ Health Branch, Centers for Disease Control and Prevention

The categories shown on this map are intended as a general guideline and should not be considered to indicate absolute risk. Elevation may vary within an area to a larger extent than this map can depict. The presence of mosquitoes may change seasonally, with increasing temperatures or rainfall, and may change over time. Travellers to destinations that cross or are near an elevation border may wish to consider the destination as an area of lower elevation. Travellers to high elevations are still at risk of getting Zika from sex.
Prevention

- All travellers should avoid mosquito bites particularly between dawn and dusk.
- There is no vaccination or medication to prevent ZIKV infection.
- It is recommended that pregnant women planning to travel to areas with a moderate risk of ZIKV transmission should consider postponing non-essential travel until after pregnancy.
- Women should avoid becoming pregnant while travelling in, and for 8 weeks after leaving an area with active ZIKV transmission or 8 weeks after last possible ZIKV exposure.
- Couples should follow guidance on prevention of sexual transmission of Zika and avoid conception while travelling and for up to 6 months on return.
- If a woman develops symptoms compatible with ZIKV infection, it is recommended she avoids becoming pregnant for a further 8 weeks following symptom onset.
- Pregnant women who visited this country while pregnant, or who become pregnant within 8 weeks of leaving this country, or within 8 weeks after last possible ZIKV exposure, should contact their GP, obstetrician or midwife for further advice, even if they have not been unwell. Further information about when to perform fetal ultrasound scanning, and, if necessary, referral to the local fetal medicine service is available.

Preventing sexual transmission

- Most cases of ZIKV are acquired via mosquito bites but cases of sexual transmission of ZIKV are occasionally reported.
- See further information for pregnant women, their partners and couples planning pregnancy.

See detailed guidance on factors to consider when assessing the risk of ZIKV.
