Worldwide rabies risk reminder

A reminder for travellers of the global risk of rabies

- This updates the news item of 17 December 2019

Human rabies is present in more than 150 countries and territories on all continents, apart from Antarctica [1].

Tens of thousands of people die each year from rabies, mainly in Asia and Africa, with over 95% of human deaths occurring in these two continents [1, 2]. Of those bitten by suspect rabid animals, 40% are children under 15 years of age. While rabies can spread to humans in saliva from any infected domestic or wild animal, the World Health Organization estimates that dogs are the main source of human rabies deaths, causing up to 99% of all human rabies transmissions [1].

During 2019, a total of four fatal imported rabies cases were reported in European travellers. In May 2019, Norway confirmed one rabies-related death following infection in the Philippines. In December 2019, three further fatal rabies cases were confirmed: one in Latvia in a traveller returning from India, one in Spain following infection in Morocco and one in Italy in a traveller bitten by a dog in Tanzania [2].

Other mammals, including bats, can also be infected with rabies and transmit it to people. As dog-mediated rabies control has improved, bats are now. There are other rabies-related viruses (lyssaviruses) that occur in bats and these can cause rabies in humans [3]. Bat lyssavirus is an emerging threat in Australia and in western Europe [1]. In 2019, the first human death from European bat lyssavirus type 1 (EBLV-1) in Western Europe was reported, in a person infected in rural France [4]. One confirmed and one suspected EBLV-1 cases were recorded in Ukraine (1977) and Russia (1985) respectively [5]. In 2020 a cat infected with West Caucasian bat lyssavirus (WCBL) was reported from Arezzo, Tuscany, Italy [6].

Advice for travellers

Rabies is spread by contact with saliva from any rabies-infected wild or domestic animal, including pets, via a bite, scratch or a lick to an open wound. In humans, rabies is usually fatal, once symptoms develop. As bats can also carry a form of rabies (bat lyssavirus), all bat bites and scratches should be considered a potential risk for rabies [7, 8]. Bat bites are often felt and not seen, and may not bleed or leave an obvious mark on the skin [7].

A course of rabies vaccine can prevent infection and death. Guidance on when protection should be started prior to travel is available on our Country Information pages but further management is still needed after all potential exposures [7].

The risk of exposure to rabies increases with longer trips and when undertaking activities such as cycling or running. Certain jobs: vets working overseas, animal control, conservation, wildlife work or volunteering in animal sanctuaries, may be very high risk.

Children are at particular risk, as they are most likely to touch animals and may not report being bitten, scratched or licked.
Before travel

Check our Country Information vaccine recommendations to see if rabies is present in bats, wild animals and/or domestic animals at your travel destination.

Consider a pre-exposure rabies vaccine course. This is especially important if you are travelling to a high-risk country and/or visiting remote areas, where medical care and rabies post-exposure treatment may not be readily available.

During travel

Avoid contact with any wild and domestic animals/pets. Remember animals that appear to be behaving normally can still be infectious:

- Do not approach any animals (including bats)
- Do not pick up ill or unusually tame animals (including bats)
- Do not attract stray animals by being careless with litter or offering food
- Remember activities like cycling or running often attract dogs

What to do if you are bitten, scratched or spat at by any animal (or bat) abroad:

- Immediate: thorough wound washing with soap and water after animal contact is crucial [1].
- If you are bitten or scratched by an animal (bats included) or if an animal (bats included) licks open skin, you must immediately flush the wound/area under a running tap for several minutes, then thoroughly wash with soap/detergent and water to remove saliva.
- Apply a disinfectant like 70% alcohol or iodine solution and cover wound with a simple dressing.
- If animal (bats included) saliva gets into your eyes, nose or mouth (i.e. if the animal coughs, spits or sneezes close to your face), wash your face thoroughly with clean water as soon as possible [7].

Get urgent medical help, even if the wound or incident seems very trivial. Seek medical attention locally, do not wait until you return to the UK. If advised, you should start rabies post exposure treatment abroad, and not wait until you get back to the UK. Prompt post-exposure treatment is needed, even if you have already had a full pre-exposure vaccine course, as further vaccine doses are required for full protection. If you had rabies vaccination before you travelled, make sure you carry your vaccine record with you.

If you did not have or did not complete a rabies vaccine course before travel, you may need treatment with a blood product called rabies immunoglobulin (which may be unavailable in some world regions), as well as a full vaccine course. Post- exposure treatment (with rabies vaccine) should be started as soon as possible, whether or not immunoglobulin is available. You may need to travel to a nearby major city or possibly another country for appropriate treatment and vaccines.

Ask for a written record of any post exposure treatment you receive overseas. If you do not feel comfortable with the medical advice you receive overseas, contact your medical insurance company.

After travel

If you had any potential exposure, however minor, contact your GP on your return to the UK. This is important, even if your received post-exposure treatment abroad and the bite/exposure was weeks
before, as you may need to continue a rabies vaccine course in the UK. If you have a record of any treatment given abroad, remember to bring this with you. Your GP will also be able to arrange for post-exposure treatment if this hasn’t been started abroad, but may be considered necessary in the UK.

**Advice for health professionals**

Health professionals advising travellers can check our [Country Information](https://travelhealthpro.org.uk) to check rabies risk and vaccine recommendations at specific destinations.

**All travellers** to countries where rabies is known or presumed to occur should be advised of the importance of first aid and of seeking urgent reputable medical attention if they are bitten, scratched or licked by any mammal. This advice is important for all travellers, whether or not pre-exposure vaccine was given.

Expert advice and guidance on assessing risk following rabies exposure including post-exposure treatment and public health management of a suspected rabies case in:

**Northern Ireland** - available from: the Public Health Agency Duty Room on 030 0555 0119

**Wales** - available from the Duty Virologist at University Hospital of Wales, Cardiff on 029 20 742 094 or 029 20 747 747 or from the Public Health Wales health protection team on 0300 003 0032.

**Scotland** - Health professionals should contact their local infectious disease unit. Information about rabies is available from [Public Health Scotland](https://www.gov.uk/government/organisations/public-health-scotland).
